

# Container Loading Problem

## A Search-Based Solution

---

AI Assignment 1 | Roll - MT24035

INDRAPRASTHA INSTITUTE *of*  
INFORMATION TECHNOLOGY  
DELHI

- Goal: Optimize loading of containers on ship.
- Minimize cost while respecting:
  - Balance constraints
  - Weight distribution
  - Destination order
- Implemented Algorithms: **BFS, Greedy Best-First, A\***.
- Input → Config file (**input.txt**)
- Output → Solution plan + cost + violations

# Problem Formulation

- **State (S):**  
 $s = \langle \text{stacks}, \text{loaded\_mask}, g, h, f \rangle$   
(stacks arrangement, placed containers, cost so far, heuristic, evaluation function).
- **Initial State ( $s_0$ ):**  
All stacks empty, no containers loaded.
- **Actions (A):**  
Place an unloaded container  $c_i$  on a valid stack  $\text{stack}_j$ .
- **Transition Model (T):**  
Update stacks, loaded\_mask, and cost after each action.
- **Goal Test (G):**  
All containers loaded **while satisfying hard constraints:**
  - Stack height  $\leq H$
  - Balance difference  $\leq B$
  - No heavier above lighter

# Problem Formulation 2

- **Goal:** Load containers into ship stacks while minimizing violations and cost.

- Ship model:

- 2 sides → Port & Starboard
- Each side → 2 stacks (total = 4 stacks)

- **Constraints:**

- Max stack height (H)

$$| \text{stack}_j | \leq H, \forall j \in \{1, 2, 3, 4\}$$

- Balance limit (B) between port & starboard

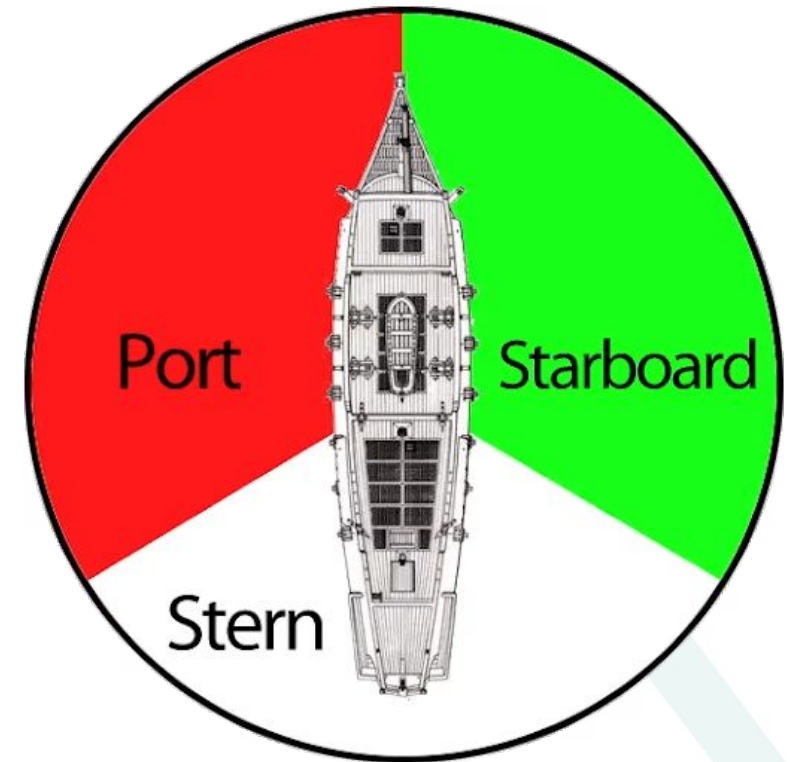

$$| W_{\text{port}} - W_{\text{starboard}} | \leq B$$

- Weight ordering (no heavier above lighter)

If  $c_i$  is below  $c_j$  in the same stack, then  $w_i \geq w_j$

- Destination order (earlier ports not blocked)

If  $c_i$  (dest  $d_i$ ) is below  $c_j$  (dest  $d_j$ ), then  $d_i \leq d_j$

# Objective Function & Assumptions

## Objective Function:

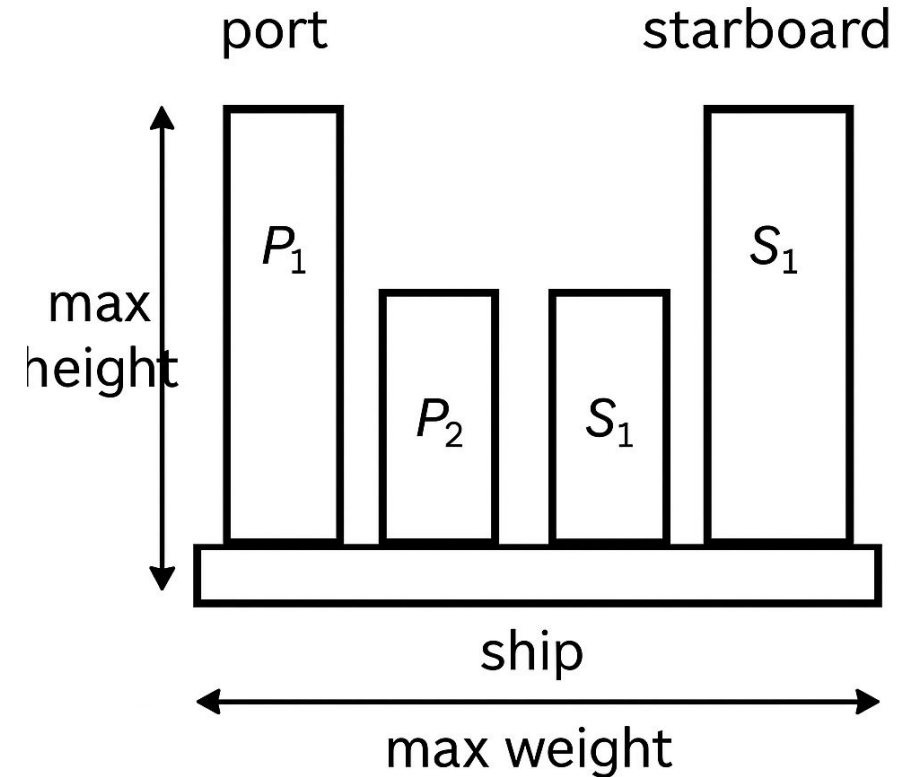

- Load cost = 1 per container
- Destination violation = +2 per violation
- Weight violation = +1
- Balance violation = forbidden (hard constraint)

$$\text{Cost}_{\text{net}} = f(s) = g(s) + h(s)$$

$$\text{Total Cost} = (\text{Number of Containers} \times 2) + (\text{Total Violations} \times 2)$$

## Assumptions:

- Ship has **4 stacks** (2 Port, 2 Starboard)
- Hard constraints: stack height  $\leq H$ , balance  $\leq B$ , no heavier above lighter
- Soft constraint: destination order (penalty if violated)

## Algorithms Used:

- **BFS**: Complete, but exponential  $\rightarrow$  impractical for large cases.
- **Greedy Best-First**: Fast, relies only on heuristic.
- **A\***: Combines cost (g) + heuristic (h), guarantees optimality.

## Data Structures:

- State =  $\langle \text{stacks}, \text{loaded\_mask}, g, h, f \rangle$
- Priority queue (Greedy & A\*)
- Queue (BFS)
- Parent map for path reconstruction

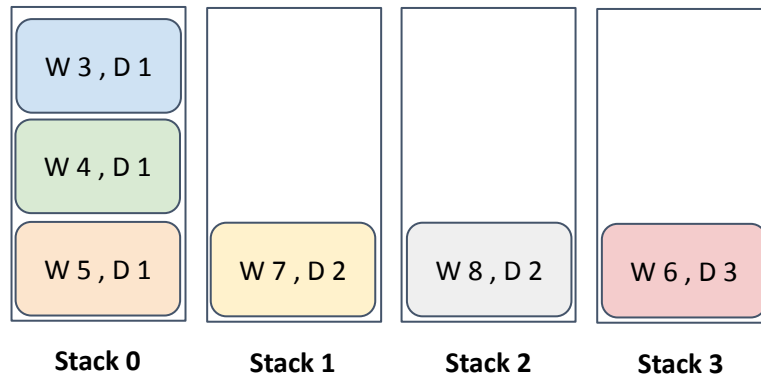

# Input & Output

Input (example input.txt):

arduino

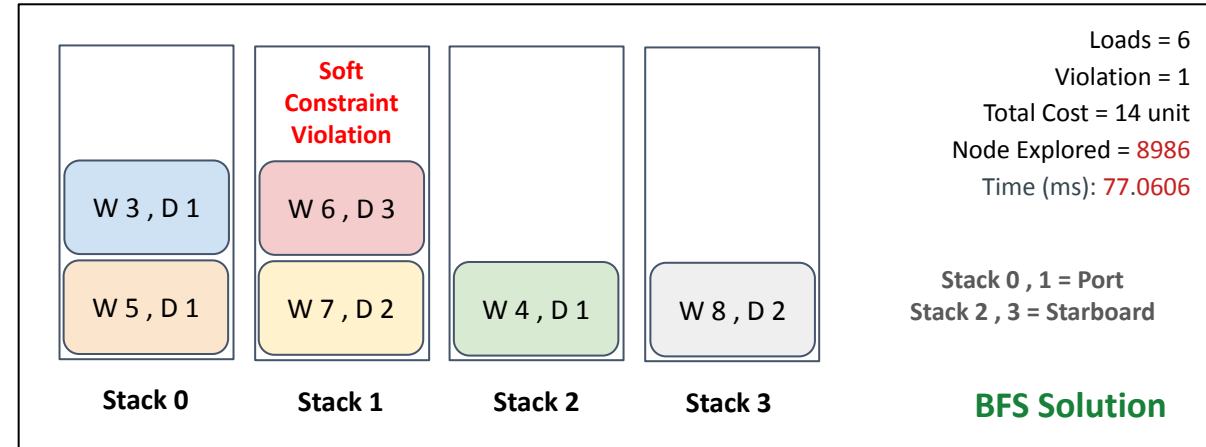

```
4 3 15 ← stacks, max height, balance limit
6       ← number of containers
5 1     ← weight=5, dest=1
7 2
4 1
6 3
8 2
3 1
```

Loads = 6  
Violation = 0  
Total Cost = 12 unit  
Node Explored = 45  
Time (ms): 0.5825

Stack 0, 1 = Port  
Stack 2, 3 = Starboard

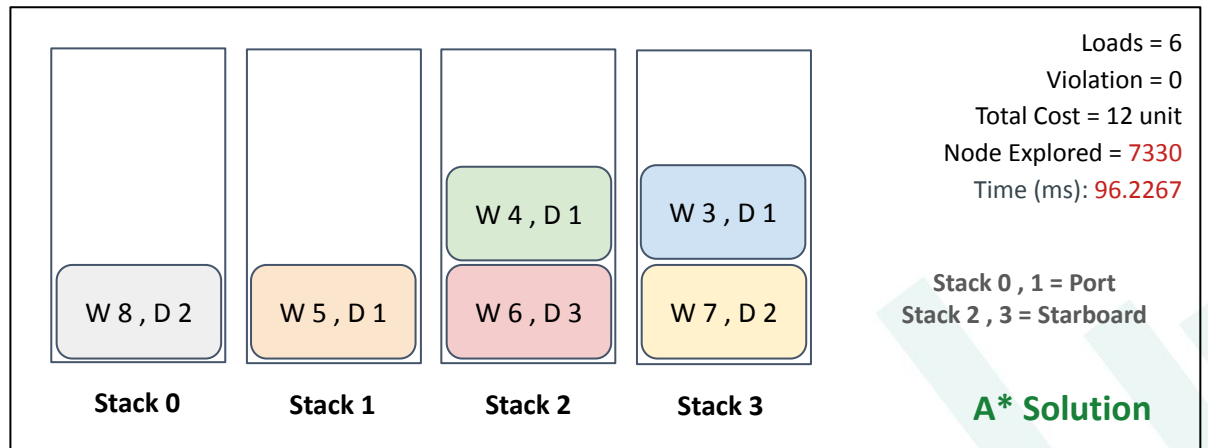

**Best First Search  
Solution**

Loads = 6  
Violation = 1  
Total Cost = 14 unit  
Node Explored = 8986  
Time (ms): 77.0606

Stack 0, 1 = Port  
Stack 2, 3 = Starboard

**BFS Solution**

Loads = 6  
Violation = 0  
Total Cost = 12 unit  
Node Explored = 7330  
Time (ms): 96.2267

Stack 0, 1 = Port  
Stack 2, 3 = Starboard

**A\* Solution**

# Conclusion

- **BFS**: Useful for correctness verification, but impractical beyond small cases.
- **Greedy**: Provides rapid approximate solutions; highly efficient if heuristics are accurate.
- **A\***: Best practical approach—balances efficiency with guaranteed optimality.
- Demonstrates how **AI search techniques** can significantly improve **real-world logistics optimization**.
